## 9 April 2016 <br> Tartu, Estonia

## Name:

## Code:

## Instructions

- Write your name and code on each page.
- You have 5 hours to work on the problems. Begin only when the START command is given.
- All results must be written in the appropriate boxes. Anything written elsewhere will not be graded. Use the reverse of the sheets if you need scratch paper.
- Write relevant calculations in the appropriate boxes when necessary. If you provide only correct end results for complicated problems, you receive no score.
- You must stop your work immediately when the STOP command is given. A delay in doing this by 3 minutes may lead to cancellation of your exam.
- Do not leave your seat until permitted by the supervisors.
- This examination has 28 pages.
- The official English version of this examination is available on request only for clarification.

## Constants and Formulae

Avogadro constant:

Gas constant:

Faraday constant: $\quad F=96485 \mathrm{C} \mathrm{mol}^{-1}$
Planck constant: $\quad h=6.626 \cdot 10^{-34} \mathrm{~J} \mathrm{~s} \quad$ Nernst equation: $\quad E=E^{\circ}+\frac{R T}{z F} \ln \frac{c_{0 x}}{c_{\text {red }}}$
Speed of light:

$$
c=3.000 \cdot 10^{8} \mathrm{~m} \mathrm{~s}^{-1}
$$

Zero of the Celsius scale:

$$
N_{\mathrm{A}}=6.022 \cdot 10^{23} \mathrm{~mol}^{-1} \quad \text { Ideal gas equation: } \quad p V=n R T
$$

n equilibrium constant calculations all concentrations are referenced to a standard concentration of $1 \mathrm{~mol} / \mathrm{dm}^{3}$. Consider all gases ideal throughout the exam.

## Periodic table with relative atomic masses

## Problem 1. Lead-Acid Battery (10 points)

The lead-acid rechargeable battery is still one of the most common batteries used in cars at the beginning of $21^{\text {st }}$ century. It has some superior characteristics, and it could be almost completely recycled. During the discharge process lead of one electrode and lead(IV) oxide of the other electrode is converted into lead sulphate. The sulphuric acid is used as the electrolyte.
a) Write the anode, cathode and total reactions of the lead-acid battery during the discharge process.

The solubility product of $\mathrm{PbSO}_{4}$ is $K_{\mathrm{sp}}=1.6 \cdot 10^{-8}$. The Latimer diagram of lead (in acid) is:

$$
\mathrm{PbO}_{2} \xrightarrow{E^{0}=1.454 \mathrm{~V}} \mathrm{~Pb}^{2+} \xrightarrow{E^{0}=-0.126} \mathrm{~V} \mathrm{~Pb}
$$

b) Is the disproportion reaction of lead(II) ions spontaneous process? Justify the answer using calculations.
c) Calculate the open circuit potential $E_{\text {cell }}{ }^{0}$ of one cell of the fully charged battery.
d) Calculate the open circuit potential ( $E_{\text {cell }}$ ) of one cell of the fully charged lead-acid battery (at $25^{\circ} \mathrm{C}$ ) which contains sulphuric acid with density $1.275 \mathrm{~g} / \mathrm{cm}^{3}$.

The open circuit potential of one cell of a lead-acid battery is $E_{\text {cell }}{ }^{0}=2.033 \mathrm{~V}$ at $5^{\circ} \mathrm{C}$.
e) Calculate the temperature coefficient $\left(\mathrm{d} E_{\text {cell }} / \mathrm{d} t\right)$ of one cell of the lead-acid battery in this temperature region.
f) Calculate the reaction enthalpy of the discharging process in the battery.
g) During the discharging of the battery:The temperature of the battery increases;The temperature of the battery decreases;The temperature of the battery does not change;The water could evaporate from the battery because of the overheating.

The output voltage of the usual lead-acid battery is 12 V , and it consists of several cells.
h) How many cells should be used to get 12 V battery?
i) Draw electrical circuit demonstrating how the individual cells are connected in the 12 V lead-acid battery.
j) Calculate the theoretical output voltage of 12 V lead-acid battery i.e. use the open circuit potential $E_{\text {cell }}$ calculated in d).

The weight of the commercial lead acid battery is $4.05 \mathrm{~kg}(9.75 \times 9.8 \times 15.1 \mathrm{~cm})$, the capacity is 12 $A \cdot h$, and the internal resistance of the battery is $100 \mathrm{~m} \Omega$.
k) Calculate the charge which could be withdrawn from the battery fully charged.

The battery was discharged, and the density of the electrolyte measured was $1.195 \mathrm{~g} / \mathrm{cm}^{3}$. The fully charged battery contained $580 \mathrm{~cm}^{3}$ sulphuric acid.
I) Calculate how much hours would it take to fully charge the battery using average current 3 A . The efficiency of charging process is $65 \%$. Assume that the amount water is constant.
$\square$
m) During the discharging the internal resistance of the battery:
$\square$ Increases;
$\square$ Decreases;
$\square$ Decreases drastically;
$\square$ Does not change.
n) The open circuit potential of the battery:
$\square$ Does not change during charging;
$\square$ Does not change during discharging;
$\square$ Increases during discharging;
$\square$ Increases during charging;
$\square$ Decreases during charging.
The efficiency of the charging process is much lower than $100 \%$ because high overvoltage is applied to the electrodes and instead of charging also the side reactions could occur: hydrogen evolution and oxygen evolution.
o) Write the equations of side reactions on the anode and cathode during the charging process.

The performance of various energy storing devices could be compared using maximum energy
density $W_{\max }=q E / m$, where $q$ is charge stored in the device, $E$ - operation voltage window and $m$ - weight of the device. Maxwell ultracapacitor BCAP3000 has the following characteristics: capacitance -3000 F , voltage window -2.7 V and mass of the device -510 g
p) For which energy storage device the maximum energy density $(\mathrm{Wh} / \mathrm{kg})$ is higher. During the discharge of the battery the potential does not change but during the discharge of capacitor the potential decreases almost linearly i.e. the average potential should be used.
q) The energy density of the lead-acid battery:
$\square$ Increases with the temperature;
$\square$ Decreases with the temperature;
$\square$ Does not change with the temperature;Increases during discharging;Increases during charging.

## Problem 2. Superconducting fullerides (10 points)

Some of the alkali metal doped fullerenes have a superconducting state. In these compounds, the alkali metal atoms fill the holes in a face-centred cubic lattice formed by the molecules of fullerene. Molecules in the fullerene crystal are also arranged in the face-centred cubic lattice.
a) Calculate the lattice parameter (a) of the fullerene crystal with a density of $1.67 \mathrm{~g} \mathrm{~cm}^{-3}$.
b) Estimate the radius of the fullerene molecule, assuming that the distance between the neighbouring molecular spheres is $d=1.42 \AA$, i.e. one $C-C$ bond length.
c) Estimate the radii of spheres (roct and r thd) that can fit the octahedral and tetrahedral holes of the fullerene crystal. Hint: Radius of a tetrahedron circumsphere is given as $r$ thd $=\sqrt{3 / 8} \cdot t$, where $t$ is the length of tetrahedron edge.
$\square$
In the figure below is shown the crystal structure of face-centred cubic $\mathbf{A}_{n} \mathrm{C}_{60}$, where $\mathbf{A}=\mathrm{Li}, \mathrm{Na}$, $\mathrm{K}, \mathrm{Rb}, \mathrm{Cs}$, and $n$ is an integer number.

d) Prove that $n=3$ for to the illustrated crystal structure. Note that all tetrahedral and octahedral holes are occupied by the alkali metal atoms.

In the Table below are given atomic $\left(r\left(\mathbf{A}^{0}\right)\right)$ and ionic $\left(r\left(\mathbf{A}^{+}\right)\right)$radii of $\mathrm{Li}, \mathrm{Na}, \mathrm{K}$, Rb and Cs , metal vaporisation enthalpies ( $\Delta H_{\text {vap }}(\mathbf{A})$ ) and ionisation energies ( $\operatorname{IP}(\mathbf{A})$ ), as well as lattice parameters of corresponding fullerides.

|  | $r\left(\mathbf{A}^{0}\right) / \AA$ | $r\left(\mathbf{A}^{+}\right) / \AA$ | $\Delta H_{\text {vap }}(\mathbf{A}) /$ <br> $\mathrm{kJ} \mathrm{mol}^{-1}$ | IP(A) / <br> $\mathrm{kJ} \mathrm{mol}^{-1}$ | $a\left(\mathbf{A}_{n} \mathrm{C}_{60}\right) / \AA$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Li | 1.52 | 0.76 | 136 | 520 | - |
| Na | 1.86 | 1.02 | 108 | 496 | 14.191 |
| K | 2.27 | 1.38 | 90 | 419 | 14.240 |
| Rb | 2.48 | 1.52 | 69 | 403 | 14.384 |
| Cs | 2.65 | 1.67 | 66 | 376 | 14.761 |

e) Calculate $\digamma_{\text {thd }}$ values for each of the alkali metal doped fullerenes. Compare the calculated values with the $r\left(\mathbf{A}^{0}\right)$ and $r\left(\mathbf{A}^{+}\right)$values from the table and prove that the alkali metal atoms are charged.

## Code:

f) Calculate the lattice energy for $\mathrm{Li}_{3} \mathrm{C}_{60}$ compound using the Kapustinskii equation: $\Delta U_{\text {lattice }}=-107000 \cdot v \cdot\left|z_{+}\right| \cdot|z-| /\left(r_{+}+r_{-}\right)$, where v is the total number of ions in the empirical formula, $z_{+}$and $z_{-}$are the charges of the individual ions, $r_{+}$and $r_{-}$are the ionic radii in pm, and the result is given in $\mathrm{kJ} \mathrm{mol}^{-1}$. Assume, $r_{+}+r_{-} \approx r_{\text {thd }}\left(\mathrm{Li}_{3} \mathrm{C}_{60}\right)+4.31 \AA$.

The first reported superconductor in the fulleride family was $\mathrm{K}_{3} \mathrm{C}_{60}$. In a year, $\mathrm{Rb}_{3} \mathrm{C}_{60}$ and $\mathrm{Cs}_{3} \mathrm{C}_{60}$ were synthesised. Preparation of $\mathrm{Na}_{3} \mathrm{C}_{60}$ was more difficult and took longer. So far it has not been possible to produce $\mathrm{Li}_{3} \mathrm{C}_{60}$. There is a correlation between the formation enthalpy values and the sequence of the $\mathrm{A}_{3} \mathrm{C}_{60}$ studies.
g) Write the $\mathbf{A}_{3} \mathrm{C}_{60}$ formula in an ascending order of the corresponding formation enthalpy absolute values. You may estimate the relative values using the data from the table.
 ${ }_{3} \mathrm{C}_{60}$ $\square$ ${ }_{3} \mathrm{C}_{60}$

## Code:

## Problem 3. The Great Drug of China (10 points)

Artemisinin is a drug that possesses most rapid action of all of the drugs used to treat Malaria. It was discovered in the 1970's by Tu Youyou, a Chinese scientist, who was awarded a Nobel Prize in 2015. She was the first Chinese Nobel Prize laureate. Initially, artemisinin was obtained by isolation from the plant Artemisa Annua. Unfortunately, no significant quantities of this plant are being grown, so in 1992 Avery et al. published a synthetic route to the Artemisinin shown below.

F

$\xrightarrow{\mathrm{O}_{3} / \mathrm{O}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 78^{\circ \mathrm{C}}}$ then $\mathrm{SiO}_{2}$ then $3 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$

## Artemisinin

## Notes:

- The empirical formula of compounds are:
- $\mathbf{B}-\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{O}_{2} \mathrm{~S}$
- D - $\mathrm{C}_{16} \mathrm{H}_{28} \mathrm{O}_{3}$
- $\mathrm{G}-\mathrm{C}_{22} \mathrm{H}_{40} \mathrm{O}_{4} \mathrm{Si}$
- All steps from $\mathbf{B} \rightarrow \mathbf{I}$ are stereoselective (reactions leading to $\mathbf{A}$ and $\mathbf{B}$ are not) thus you must draw the major enantiomers of all of the intermediates from $\mathbf{C}$ to $\mathbf{I}$.
- LDA and LDEA are bulky bases.
- Conversion $\mathbf{G}$ to $\mathbf{H}$ is the Claisen rearrangement reaction.

## Code:

a) Draw the structures of the compounds $\mathbf{A}$ to $\mathbf{E}$, paying particular attention to the stereochemistry of the compounds C, D, and E.

b) Propose a mechanism for the conversion $\mathbf{A}$ to $\mathbf{B}$.
c) Propose a mechanism for the conversion E to F. Note, that DMF is not the solvent of the reaction and that there is no racemisation. You can use abbreviations for the mechanistically unimportant structural features.

DMF - dimethylformamide
d) What is the major driving force of the reaction $\mathbf{E} \rightarrow \mathbf{F}$ ?
$\square$ Product can form hydrogen bonds with the solvent.Having three oxygen in the molecule is better than having two.Nitrogen is produced and released during the reaction.Product is more conjugated than the starting material
$\square$ Compound $\mathbf{E}$ is harmful, compound $\mathbf{F}$ is not.
e) Draw the structures of the compounds $\mathbf{G}$ and $\mathbf{H}$. Pay attention to the stereochemistry. Use abbreviation if necessary.

| G | $\mathbf{H}$ |
| :--- | :--- |
|  |  |

f) Propose the mechanism for the conversion $\mathbf{G} \rightarrow \mathbf{H}$. Use abbreviations for the mechanistically unimportant structural features.
g) Assign the relative configuration ( $R$ or $S$ ) of all of the stereocentres for the compounds $\mathbf{G}$ and $I$.

| G | $\mathbf{I}$ |
| :--- | :--- |
|  |  |
|  |  |
|  |  |

## Problem 4. The biggest coins in the world (10 points)

Beginning of $17^{\text {th }}$ century was turn point in Sweden economics as it lost control over silver mines in Norway but added Baltic region (including Tartu and Riga) to their territories. The Mine of Falun had rich stores of the raw material, and Swedish king decided to produce copper coins (plates) of value close to the value of silver coins The first copper coins were issued in 1624, the weight of one coin was 19.7 kg and the volume of $2205 \mathrm{~cm}^{3}$. Copper has face centred cubic lattice (fcc) with the lattice parameter of 361.5 pm . In nature copper usually is found as sulphide minerals, for example - chalcopyrite (contains $35 \%$ of copper by mass and iron) and chalcocite (contains $80 \%$ of copper by mass).
a) Calculate chemical formula of chalcopyrite and chalcocite.

| Chalcopyrite calculations: | Chalcocite calculations: |
| :--- | :--- |
|  |  |
|  |  |

Nowadays copper is extracted even from ores where copper content is as small as $0.60 \%$.
b) Write balanced reaction equations showing extraction of copper from ore containing chalcocite, if it is known that copper(I) oxide is formed as intermediate.
c) Calculate the mass of ore to be recycled to produce copper, which is necessary for the production of one Swedish coin.

## Code:

Copper(I) oxide is reddish-brown substance; it is used as a component of some antifouling paints. Copper(I) oxide is reduced when it is mixed with chalcocite, free copper, and sulphur dioxide is formed.

| Substance and its <br> state | $\mathrm{Cu} 2 \mathrm{O}(\mathrm{s})$ | Chalcocite(s) | $\mathrm{Cu}(\mathrm{s})$ | $\mathrm{SO}_{2}(\mathrm{~g})$ |
| :--- | :--- | :--- | :--- | :--- |
| Standard enthalpy of <br> formation $/ \mathrm{kJ} \mathrm{mol}$ <br>  <br> -1 | -168.6 | -79.5 |  | -296.8 |
| Molar standard <br> entropy $/ \mathrm{J} \mathrm{mol}^{-1} \mathrm{~K}^{-1}$ | 93.1 | 120.9 | 33.2 | 248.2 |
| Melting point $/{ }^{\circ} \mathrm{C}$ | 1232 | 1130 | 1084 |  |
| Enthalpy of fusion / <br> $\mathrm{kJ} \mathrm{mol}^{-1}$ |  |  | 13 |  |

d) Use data in table and calculate Gibbs energy of copper(I) oxide reduction reaction at standard conditions $\left(25^{\circ} \mathrm{C}\right)$
e) Fill table below indicating a sign of thermodynamic function of the reduction reaction.

| Temperature | $0^{\circ} \mathrm{C}$ | $500^{\circ} \mathrm{C}$ | $1000^{\circ} \mathrm{C}$ |
| :--- | :--- | :--- | :--- |
| Sign of $\Delta H$ |  |  |  |
| Sign of $\Delta S$ |  |  |  |
| Sign of $\Delta G$ |  |  |  |

f) Use thermodynamic data in the Table and calculate Gibbs energy of copper(I) oxide reduction reaction at $1100^{\circ} \mathrm{C}$ temperature.
$\square$
Young chemist Grzegorz decided to reuse copper coin; he made up the electrolytic cell, and attached Swedish copper coin and almost pure copper wire as electrodes and used copper(II) nitrate as the electrolyte.
g) Which electrode (anode / cathode) was made from Swedish copper coin? Write corresponding half reaction.

Circle the correct answer: anode / cathode
Half-reaction:
h) How long (in hours) does, it takes to recycle all Swedish coin if electrolysis is performed with 1.00 A current?
i) Copper nowadays is used for the preparation of internet cables. Calculate the length of copper fiber of diameter 0.1 mm which can be produced from Swedish copper coins.
j) How many copper coins it is necessary to recycle to produce a copper fibre with a length of 600 km (distance from Tallinn to Vilnius via Riga).
$\square$
Most part of copper used in nowadays is recycled. Another method used in recycling process is dissolution of copper in nitric acid. Nitric acid reacts with copper in two ways given bellow
k) Complete and balance both oxidation-reduction reaction equations.
(1) $\mathrm{Cu}+\mathrm{HNO}_{3} \rightarrow \mathrm{NO}+$ $\qquad$
(2) $\mathrm{Cu}+\mathrm{HNO}_{3} \rightarrow \mathrm{NO}_{2}+$ $\qquad$

Scientific papers state that complete oxidation of carbon monoxide can be achieved at room temperature over unsupported copper(II) oxide catalyst by a careful and controlled generation of the oxide. The Figure below shows natural logarithm of oxidation reaction rate as a function of $1 / T$, where $T$ is the temperature in Kelvin (K).

I) Use the data in the Figure and calculate the activation energy for the oxidation of carbon monoxide.
m) Enthalpy of complete combustion of carbon (in solid state as graphite) is $-393 \mathrm{~kJ} / \mathrm{mol}$, but standard enthalpy of formation of carbon monoxide is $-111 \mathrm{~kJ} / \mathrm{mol}$. Sketch energy diagram of carbon monoxide oxidation reaction and state exact energy difference values where possible.
$\square$

Copper is still used in the production of coins. Young chemist Grzegorz decided to prove it and analysed 2 EUR coin by x-ray diffraction. Diffraction pattern for analysed coin is shown below.

Figure Diffraction pattern of 2 EUR coin
Use Bragg equation

$$
d=\frac{\lambda}{2 \cdot \sin \frac{2 \theta}{2}}
$$

where $d$ - distance between diffraction planes (nm); $\lambda$ - wavelength of x-rays ( 0.15408 nm ), $2 \theta$ diffraction angle.
and

$$
d=\frac{a}{\sqrt{h^{2}+k^{2}+l^{2}}}
$$

where $d$ - distance between diffraction planes (nm), a - lattice parameter, $h, k$ and $I$ - Miller indices. For the face-centred cubic lattice (fcc) only diffraction peaks where all Miller indices are odd numbers or all Miller indices are even numbers are allowed.
n) Indicate in diffraction pattern which peak(s) correspond to copper and state, at least, one set of Miller indices for each of the copper peaks.

| Diffraction angle $/ \circ$ |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
| $d /$ |  |  |  |  |
| Miller indices <br> (if any) |  |  |  |  |
| Signal corresponds to <br> copper (YES / NO) |  |  |  |  |

## Problem 5. "My precious" (10 points)

Silver jewellery is seldom made of absolutely pure silver. Different alloys are usually used instead of pure silver. Chemistry student Grzegorz decided to analyse his mom's silver ring and find out how much copper it contains because he knew that this ring had some copper impurity. So, Grzegorz dissolved 1.00 g of that ring in a small volume of concentrated nitric acid and diluted the solution to 25 ml . Let's call it solution A. It was coloured, because of that the student decided to calculate the amount of copper in the solution using its feature to absorb visible light. He measured the absorbance of the solution using the photometer.
 Usually, molar extinction coefficients of metals salts solutions are less than $1000 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$. In this problem use Bouguer-Beer-Lambert law:

$$
\log \left(I_{0} / I\right)=A=\varepsilon c l
$$

In his measurements, Grzegorz used the photometer, which can measure the smallest value of absorption $A=0.001$.
a) Calculate the smallest concentration of hypothetical substance $\mathbf{X}$ that can be measured by this device when $\lambda=600 \mathrm{~nm}, \varepsilon 600=3.25 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$ and $I=1 \mathrm{~cm}$ ?
b) Light filters are usually used in photometers to generate the monochromatic light beam. What is the colour of the filter if it absorbs only violet ( 390 nm ) light?
$\square$ Blue;
$\square$ Green;Violet;
$\square$ Red.
The absorbance spectrum of hypothetical substance $\mathbf{X}$ is given in the figure below.

## Code:

c) Draw the absorbance spectrum of the best suitable filter for the substance $\mathbf{X}$ analysis. "Best suitable" means that, when that filter is used, Lambert-Beer law holds, the smallest possible substance $\mathbf{X}$ concentrations can be measured, and the most accurate results are obtained.

To find out copper concentration in solution $\mathbf{A}$, he used "addition method". In the beginning, Grzegorz measured the absorbance of solution $\mathbf{A}$ in 3.00 cm cuvette at $\lambda=700 \mathrm{~nm}$ wavelength. The photometer showed 0.240 . Assume that silver ions do not absorb visible light.
d) Calculate, what fraction (in percent) of initial light intensity is transmitted through the sample.

After that, Grzegorz weighed 5.12 g of copper sulphate pentahydrate, dissolved it in a20 ml volumetric flask and diluted to the mark (let's call it solution B). Then he mixed 15 ml of solution A and 1 ml of solution $\mathbf{B}$ and also measured the absorbance of this mixture in 1.00 cm cuvette at $\lambda=700 \mathrm{~nm}$ wavelength. The photometer showed the value $A=0.694$.
e) Calculate the mass fraction (in percent) of copper in the ring.

Grzegorz was so interested in his mom's jewellery analysis that he decided to measure the quantitative composition of mom's earring, which was made from monelmetal (copper-nickel alloy). So the student dissolved a piece of that earring in concentrated nitric acid (let's call it solution C) and measured the absorbance of solution $\mathbf{C}$ in 1.00 cm cuvette at $\lambda_{1}=400 \mathrm{~nm}$ wavelength and at $\lambda_{2}=800 \mathrm{~nm}$ wavelength. He also measured the absorbance of earlier prepared standard solution $\mathbf{D}$ in which $\left[\mathrm{Cu}^{2+}\right]=0.025 \mathrm{M}$ and $\left[\mathrm{Ni}^{2+}\right]=0.055 \mathrm{M}$. The results he got are listed in the Table below. The Figure below shows the molar extinction coefficient dependence on wavelength for copper and nickel. Molar extinction coefficient for nickel at wavelength 800 nm $\varepsilon_{800}=4.41 \mathrm{M}^{-1} \mathrm{~cm}^{-1}$.

Table. Absorbance dependence on solution and $\lambda$

| $\lambda, \mathrm{nm}$ <br> Solution | 400 | 800 |
| :---: | :---: | :---: |
| C | 0.765 | 0.548 |
| D | 0.894 | 0.638 |

f) Using data given above, find out the composition (in mass percent) of the earring.

Grzegorz's friend Piotr told Grzegorz about metal complexes. Piotr pointed out that it is better to evaluate metal concentrations in solutions using organic compounds that make complexes with metal ions. Due to recent changes in safety rules Grzegorz's school was trying to get rid of carcinogenic cobalt (II) chloride. So Grzegorz waited for the right moment and deliberately took the salt as he came up with an idea to analyse cobalt (II) complex formation reaction.

The complex between $\mathrm{Co}(\mathrm{II})$ and the ligand $\mathbf{R}$ was investigated photometrically.A green filter at 550 nm (the wavelength of absorbance maximum for the complex) was used for the measurements. Assume that only the complex absorbs the light. The initial cation concentration was $2.5 \cdot 10^{-5} \mathrm{~mol} / \mathrm{L}$ in solutions with different concentrations of R. The absorbance data ( 1 cm cell) were obtained as follows:

Conc. R

| $(\mathrm{mol} / \mathrm{L})$ <br> $\times 10^{-5}$ |  | Absorbance (A) |
| :--- | :--- | :--- |
|  |  |  |
| 1.50 |  | 0.106 |
| 3.25 |  | 0.232 |
| 4.75 |  | 0.339 |
| 6.25 |  | 0.441 |
| 7.75 |  | 0.500 |
| 9.50 |  | 0.523 |
| 11.5 |  | 0.529 |
| 12.5 |  | 0.531 |
| 16.5 |  | 0.529 |
| 20.0 |  | 0.530 |

g) Draw a graph of absorbance versus $\mathbf{R}$ concentration and determine the ligand to cation ratio for the complex.

h) Determine the value of molar extinction coefficient $\varepsilon_{550}$ for the complex from g ) question.
i) Which one of the following statements best describes the advantage of using complexes in photometry?
$\square$ To increase the molecular mass of analyst;
$\square$ To enhance the solubility of the analyst;
$\square$ To increase molar extinction coefficient of the analyst;
$\square$ All of the above.

## Problem 6. Ayahuasca (10 points)

Ayahuasca is a brew made out of $B$. cappi vine. This brew is used orally as a traditional spiritual medicine in ceremonies in South America. It can be mixed with leaves containing DMT for a significantly different - psychedelic effect. $\mathrm{N}, \mathrm{N}$ dimethyltryptamine (DMT) is a psychedelic compound of the tryptamine family, and it is a structural analogue of serotonin and melatonin. It is interesting to notice that DMT taken orally is broken down by the enzyme monoamine oxidase through a process called deamination and is quickly inactivated orally unless combined with a monoamine oxidase inhibitor.

Harmala alkaloids are monoamine oxidase-inhibiting beta-carbolines. Two of the three most studied harmala alkaloids in the B. caapi vine are harmine and harmaline. In this problem, you have to complete the synthesis of harmine and harmaline given bellow.

11

Hints: anethole exhibits cis/trans isomerism; products $\mathbf{1}$ and 2 are both aromatic compounds; $\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CC}_{3} \mathrm{~F}_{7}\right) 4$ is used as an intramolecular reaction catalyst; compound 5 has broad signal in IR spectra ( $\sim 3000 \mathrm{~cm}^{-1}$ ) whereas compound 6 does not.
a) Investigate a ${ }^{1} \mathrm{H}$ NMR spectrum (which is given bellow) of the starting material - anethole. Draw the molecule, assign the peaks to the protons and mark signal multiplicity ( $s$ for singlet, $d$ for doublet, $d d$ for doublet of doublets, etc.).

## Code:

b) Propose an alternative synthesis of p-anisaldehyde (compound 2). Use p-cresol (4methylphenol) as a starting material.
c) Name a purification procedure that could be used to separate a mixture of products $\mathbf{1} \& 2$.
d) Identify compounds 1-10 and 12 and draw their structures.

| 1 | 2 | 3 |
| :--- | :--- | :--- |
| 4 | 5 | 6 |
| 8 | 9 | 10 |
| 12 |  |  |

DMT in one's mouth can be metabolized in at least two different ways. One pathway is governed by a monoamine oxidase and aldehyde dehydrogenase enzyme activity (MAO-ADH). Other product is obtained through other modifications. Two products are given bellow.

e) MAO-ADH enzyme is hidden under the letter:
$\square \mathrm{B}$;
$\square$ Both;None of these are right.
